- Ways to host backend files/user auth system

There are a couple ways that we could host the backend files/ auth

There are things such as -

- Self-hosted solutions
 - This is where you use Open Source Auth Servers: Gluuu, FreeIPA, these are ran on your own infrastructure giving full control over authentication.
 - You then implement custom auth: develop custom auth tailored to your needs using frameworks and libraries provided by your IDE, e.g., Node.js uses libraries like passport.
- Cloud Based Solutions -
 - Amazon Web Services - weve tried this and ran into problems because of the paywall
 - Google Cloud Platform(GCP) - This provides SQL for databases and Firebase Authentication for managing user identities, need to look further into whether or not theres a paywall
 - Google Cloud provides \$300 credits to use over a 90 day period which may be very useful for our project
 - Microsoft Azure - Offers Azure SQL dB services and Azure Active Directory for authentication, offers a 12 month free trial which gives unlimited access to all features
- Containerized Solutions -
 - Docker - Docker is a platform that allows you to package applications and dependencies into containers, making it easier to deploy and run applications consistently across different environments. This is a free

option, and I've already got it downloaded and setup due to it being used in another module.

- Kubernetes is similar to docker - However you have to pay for the cloud service used on Kubernetes, so the paywall may block this method of hosting.
